

FIG. 1. Hard-wall purification from a maximally mixed active slab, $N_x = 20$, $\alpha_1 = 1$, $\alpha_2 = 30$, $n_{\text{shell}} = 1$, with perfect correction and 100 independent Born trajectories per size. (a) Mean total entropy per N_y . (b) Mean entropy contours summed over y and orbitals, at the walls ($x = 5, 15$) and center ($x = 10$). Bands denote one sample SEM. (c) Mean endpoint gap $\Delta = \min_j |\text{atanh}(a_j)| / (4N_y)$, with centered covariance eigenvalues a_j and SEM bars. The fit over all shown sizes gives $\Delta \propto N_y^{-1.11 \pm 0.04}$. (d) Endpoint mode probability density at $N_y = 30$, $T = 4N_y$: orbital-summed probabilities are averaged over modes with $10^{-9} < \nu_j < 1 - 10^{-9}$ within each trajectory, then equally over trajectories. The density sums to one; colors are linear. All runs end at $T = 4N_y$.
